

Legg–Calvé–Perthes disease

Learning objectives

Introduction to LCPD

It is a self limiting disorder of the hip produced by ischemia and varying degrees of necrosis of the femoral head.

Epidemiology

- Incidence : 1:1000
- Usual age : 4-8 years
- Boys:girls – 5:1
- Higher incidence in Caucasian, Chinese, Japanese, Inuits, Northern Europe

Aetiology-

Coagulation disorders.

Arterial status of femoral head.

Abnormal venous drainage.

Abnormal growth and development.

Trauma.

Hyperactivity or attention deficit disorder.

Genetic component.

Environmental influences.

As a sequel to synovitis.

Pathogenesis

- Ischemia of femoral head

Up to 4 months	<div><div>1. Metaphyseal vessels</div><div>2. Lateral epiphyseal</div><div>3. Scanty vessels in ligamentum teres</div></div>
4-7 years	<div><div>1. Lateral epiphyseal vessels</div><div>2. Metaphyseal supply DISSAPEAR</div></div>
7 years	<div><div>1. Vessels in ligamentum teres have developed</div></div>

Susceptible to ischemia, as it depend entirely on lateral epiphyseal vessel.

Pathology-Stage 1-Ischaemia

Pathological process → 3-4 years

- All/part of bony nucleus of femoral head is dead
- Cartilaginous part – remains viable and thicker
- Thickening and edema of synovium and capsule

Stage 2 – revascularization and repair

Stage 3 – Distortion and remodeling

- Repair process
 - Rapid and complete : shape is restored
 - Tardy : bony collapse and growth distortion

Clinical feature

Symptoms

- Typically male – 4-8 years
- Painless limping – continues for weeks or recur intermittently
- Pain in groin, thigh and knee – activity related, relieved by rest

Signs

- Hip pain with passive range of movement
- Reduced range of movement (abduction & internal rotation)
- Hip flexion contracture
- Leg length discrepancy
- Mild muscle wasting – thigh, calf,
- Trendelenburg test ; positive

Investigation

- X-ray of both hips (AP & Frog lateral view)
- Bone scan
- CT scan – follow up
- Arthrography : to see congruity, head deformity and determine method of treatment
- Blood inflammatory marker
 - FBC
 - ESR
 - CRP

X-ray

- Widening of joint space
- Sclerosis
- Necrotic phase : increase density of ossific nucleus
- Fragmentation : alternating patches of density and lucency
- Lateral uncovering of femoral head
- Acetabular remodelling

Waldenström classification based on radiographic changes

Stage 1 (increased density)

- ossific nucleus smaller and denser
- subchondral fracture
- radiolucencies in the metaphysis

Caffey's sign

- Subchondral fracture in the anterolateral aspect of the femoral capital epiphysis
- Produces crescentic radiolucency

Waldenström classification based on radiographic changes

Stage 2 (fragmentation and revascularization)

- lucency in epiphysis
- pillars are demarcated
- metaphyseal changes resolve
- acetabular contour change

Stage 3 (healing or reossification stage)

- new bone formation
- homogenous epiphysis

Stage 4 (remodelling)

- femoral head is reossified and remodels
- acetabular remodelling

Classification

According to radiologic stage of disease –

Waldenström classification

According to prognostic outcome –

– **Herring lateral pillar**

According to defining outcome –

Stulberg classification

The Herring lateral pillar classification–

lateral pillar not affected	>50% of height of lateral pillar preserved	<50% of height of lateral pillar preserved
-----------------------------	--	--

Herring stage A

Good prognosis

Herring stage B

Herring stage C

Prognostic features

- Child under 6 years – excellent
- Age on higher side
- Progressive loss of hip motion more so abduction
- Obese child
- Progressive uncovering of the epiphysis

Differential diagnosis

- Multiple epiphyseal dysplasia
- Spondyloepiphyseal dysplasia
- Mucopolysaccharidoses
- Hypothyroidism
- Other Causes of Avascular Necrosis
 - Sickle cell disease
 - Steroid medication
 - Sequela of traumatic hip dislocation
 - Treatment of developmental dysplasia of the hip
- Septic arthritis

D/D-Hypothyroidism

D/D-Multiple Epiphyseal dysplasia

Management-Principles

1. Prevent deformity to femoral head before remodelling phase
2. Restore and maintain ROM
3. Concept of containment
4. Relief of symptoms

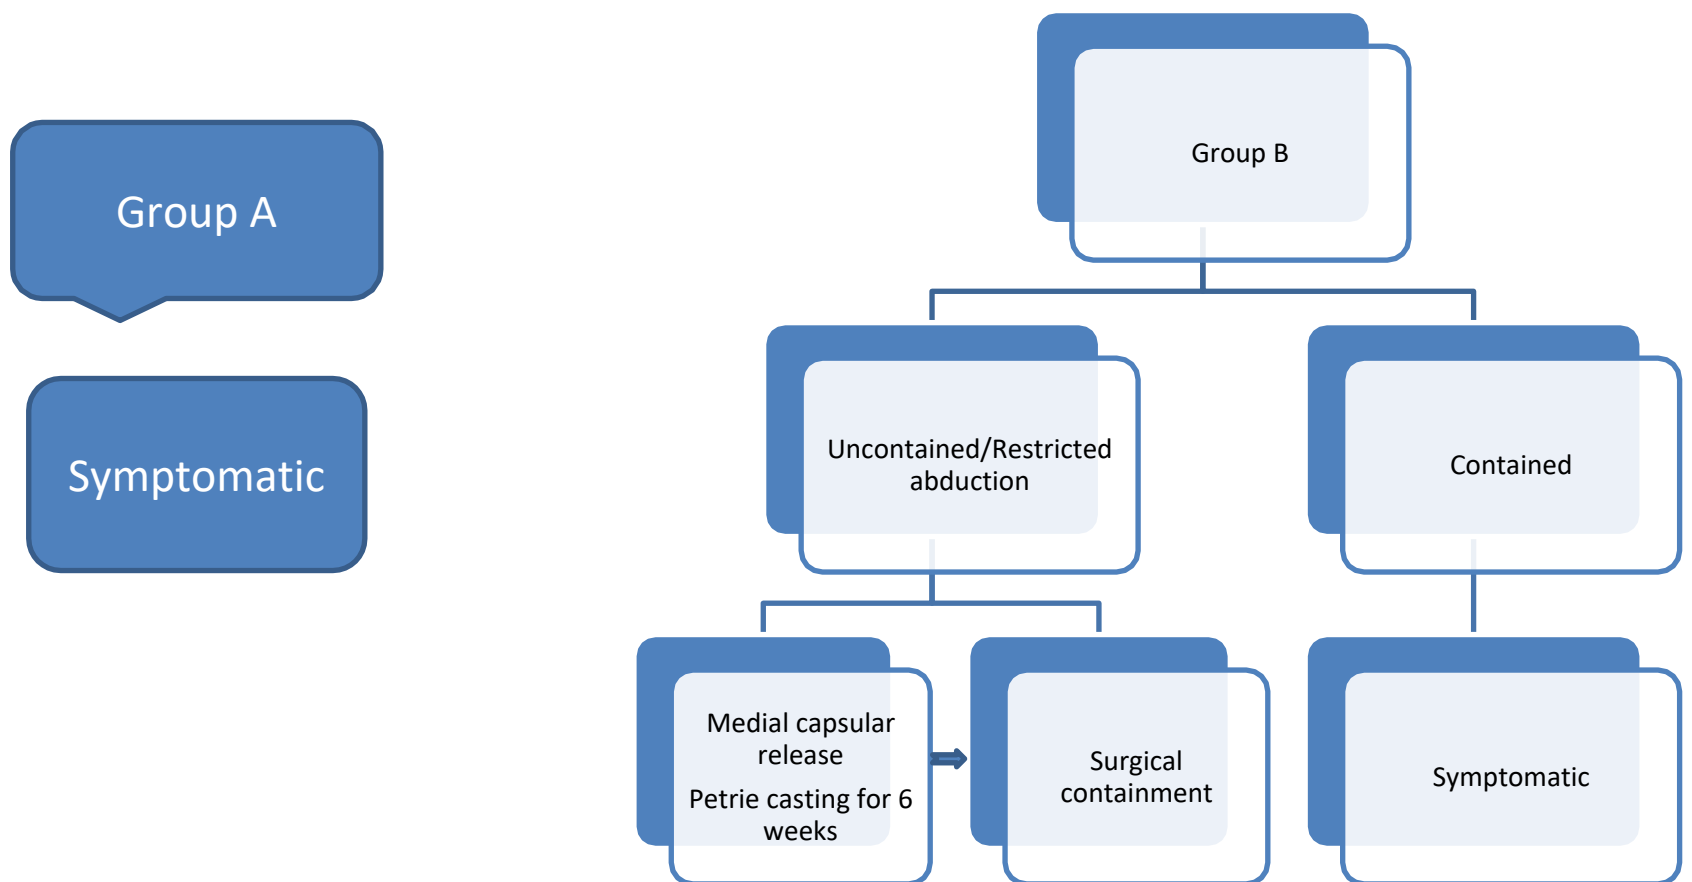

Guidelines to treatment

- Decision are based on :
 - Stage of disease
 - Prognostic x-ray classification
 - Age and clinical feature particularly range of abduction and extension

Guidelines by Herring (1994)

- Child <6 years(age at onset)
- Symptomatic treatment-Rest/Analgesics
- Operative intervention-no added benefit

Age at onset 6-8 years

Age at onset 8-11 years

- Surgical treatment gives better outcome
- In very early stage when fragmentation yet to appear, do perfusion MRI
- If severe ischaemic changes-Surgical containment
- Group B, B/C-Surgical containment

Symptomatic

- Pain control
- Hospitalization for bed rest and short period traction
- Gentle exercise to maintain movement

Containment

Harrison and Menon stated ;

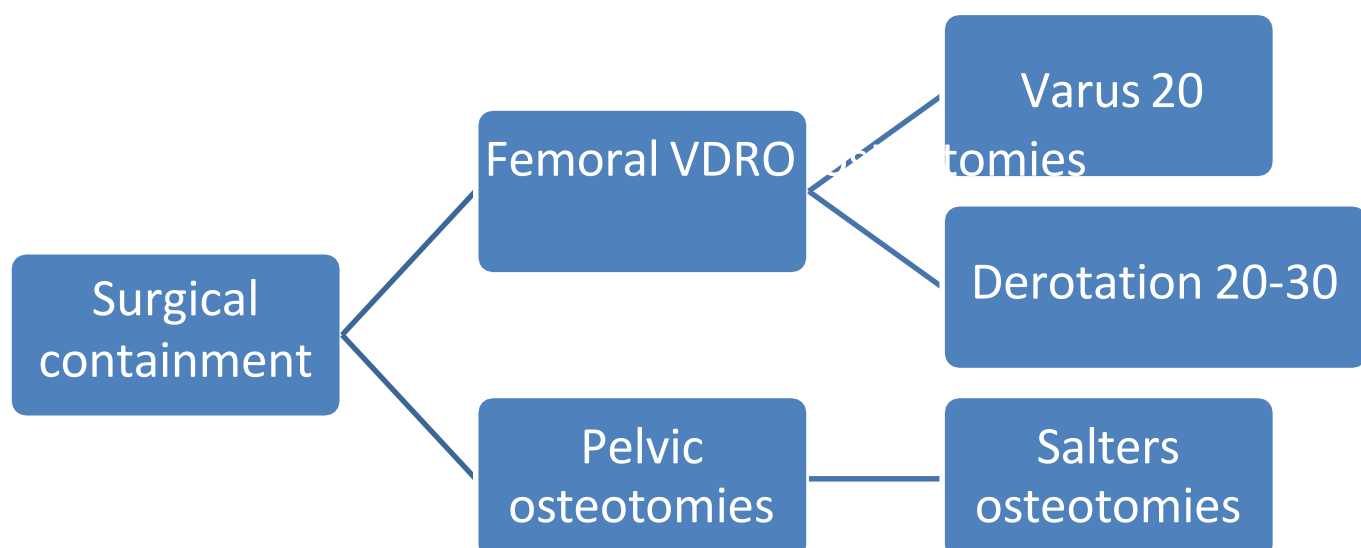

‘if the head is contained within the acetabular cup, then like jelly poured into a mold the head should be the same as the cup when it is allowed to come out after reconstitution ‘

Containment – non operative

Containment – surgical

- Done before irreversible deformation of femoral head occurs (early in fragmentation stage)

Femoral varus derotational osteotomy

Pelvic osteotomy

Innominate osteotomy using quadrangular Graft (Canale et al)

Salter innominate osteotomy

Summary

3 Phases of Perthes

Initial Phase

everything looks ok
but this hip is unhappy
("Painful")

Fragmentation Phase

the hip bone is soft
from the lack of nutrients
so it starts to collapse

Remodeling Phase

the hip grows back!
